# Cambio

## MUSD payments with verified usernames and signed payment requests

A non-custodial payment application on Mezo Testnet

# The payment problem

**People copy addresses.**
**Recipients trust screenshots.**
**Edited payment links can redirect funds.**

Cambio gives MUSD users a recipient they can resolve,
a request they can authenticate and a payment they can check.

# The core payment experience

01 Claim a username with a wallet signature
02 Sign and share an MUSD request
03 Review and approve the transfer in the wallet
04 Open the independent settlement proof

The receiving wallet keeps control of its funds.
Cambio never holds a private signing key.

# Meaningful Mezo integration

## MUSD transfers settle on chain 31611

BTC pays network fees. MUSD uses its verified token contract.

Signed requests bind the recipient, amount, token and request ID.
Settlement checks exact calldata and the MUSD Transfer event.

Swaps use the Mezo router. Testnet liquidity can be off-peg or empty.

# Engineering evidence and limits

**143**

**unit, integration and UI tests passed**

Firestore rules and atomic identity tests pass against the emulator. Production browser tests cover signature, tampering and live reads. Chain checks are read-only. A real payment proof remains unrecorded.

# Submission status and next milestones

## Testnet candidate with explicit release gates

Before submission: deploy with durable identity and record a real payment.

Proposed next phase: validate a small merchant pilot and mobile wallets.
Then: improve indexing coverage and review wallet dependencies.
Any mainnet work follows a separate security review.
